## ( *Ortho*-alkynyl-benzoates glycosyl donors, for glycosylation under the catalysis of gold(I) complex )

### 1. General information of the glycosyl donors

The *ortho*-alkynylbenzoates are a new type of glycosyl donors (Fig. 1), which undergo glycosylation in the presence of a catalytic amount of a gold(I) complex. The carbohydrates for glycosylation can be *D*-glucopyranose, *D*-glucosaminepyranose, *D*-galactopyranose, *L*-rhamnopyranose, *L*-arabofuranose, *D*-ribofuranose, etc. Other carbohydrate *ortho*-alkynylbenzoate donors can also be prepared according to the carbohydrate chemists' needs through the same synthetic method.

Sugar = *D*-glucopyranose, *D*-glucosaminepyranose, *D*-galactopyranose, *L*-rhamnopyranose, *L*-arabofuranose, *D*-ribofuranose, etc.

R<sub>1</sub> = n-Bu, cyclopropylethynyl

Fig.1

Depending on the type of carbohydrates and the preparative conditions as well, a varied  $\alpha:\beta$  anomer ratios of the donors are attained. Experiments showed little difference between the pair of anomers in glycosylation in accord with the glycosylation mechanism; thus the anomeric mixtures need not to be separated but can be directly used in the glycosylation reactions. For details of the methodology, see the followed references.
